

"Corner guard for cases and similar transport containers and a transport container provided with said corner guard"

5 The present invention relates to a corner guard for box-type containers, such as cases, transport boxes and the like, comprising a caplike corner-protecting element to be fitted externally over a container corner.

10

Furthermore, the invention also relates to a container provided with at least one (and up to eight) such corner guard or guards.

15 Corner guards of such type are known; they commonly consist of a sheet-metal material having three wall sections which are each at right angles to one another and are intended to bear on three container walls adjoining a container corner, the wall sections usually 20 being screwed, riveted or adhesively bonded to the container walls from outside. Such corner guards are intended to provide the container corners with a certain degree of protection from impact-related damage. However, impact-related damage is frequently 25 caused to the contents of the container during practical use, especially if sensitive equipment or items form the contents.

30 The object on which the present invention is based is to improve a corner guard of the aforementioned type in such a way that a container equipped with such a guard is not only protected itself from impact-related damage in the corner region, but it is also possible to significantly reduce impact-related damage to the 35 container contents.

This is achieved according to the invention by means of at least one elastic intermediate corner element for impact-absorbing arrangement between the corner-

protecting element and the container corner. According to the invention, the corner-protecting element is thus completely elastically disconnected from the container by way of the intermediate corner element, with the 5 result that impacts acting against the corner-protecting element from outside cannot be transmitted directly to the container but are absorbed elastically by the intermediate element, the impact energy being damped (consumed) by elastic deformations. As a 10 consequence, the respective container contents are also advantageously protected from impacts, which means that a container equipped with corner guards according to the invention is optimally suitable for accommodating impact-sensitive items and equipment.

15

For reasons in particular of manufacturing, handling and assembly it is advantageous if, prior to being fastened to the respective container, the corner-protecting element has already been connected to the 20 intermediate corner element to form a unit. For this purpose, a nonreleaseable, for example cohesive, connection is possible, for example by adhesive bonding, welding or else by integral production from plastic as a two-component molding. However, a 25 nonpositive and/or positive connection, in particular a plug-type connection, is also advantageous since use can thus be optionally made of intermediate corner elements which differ in terms of their elasticity and impact-absorbing properties. Moreover, there is also 30 the possibility of simple replacement at any time.

The corner guard according to the invention can likewise be fastened nonreleaseably, for example by adhesive bonding, to or on the respective container 35 corner. However, the corner-protecting element, together with the intermediate corner element, can preferably be fastened releaseably in the region of the container corner. In a further preferred refinement, this fastening operation is carried out in the region

of a container corner opening from the inside of the container, in particular by means of a retaining screw which engages in a retaining hole in the corner-protecting element, preferably by means of an 5 additional inner elastic pressing element in such a way that the corner-protecting element is disconnected from the container in terms of elastic impact absorption by way of the intermediate corner element and the pressing element. The edges of the container walls adjoining the 10 corner opening are thus retained by being clamped exclusively between the elastic components of the corner guard according to the invention, with the result that the corner-protecting element is thereby retained elastically (elastically suspended) on the 15 container.

Further advantageous design features of the invention are contained in the subclaims and the description which follows.

20 The invention will be explained more precisely with the aid of a preferred exemplary embodiment illustrated in the drawing, in which:

25 fig. 1 shows a perspective partial view of a container in the region of a container corner which is provided with a corner guard according to the invention,

30 fig. 2 shows a perspective view of the arrangement according to fig. 1 from the inside of the container,

35 fig. 3 shows a perspective exploded representation pertaining to fig. 1 (view from the outside of the container), and

fig. 4 shows a perspective exploded representation pertaining to fig. 2 (from the inside of the

container).

A corner guard 1 according to the invention is fastened in the region of a container corner 2 (fig. 3) to a 5 container 4, only part of which has been represented. The container 4 takes the form of a case, transport box or the like, three container walls 6, usually at right angles to one another, in each case adjoining one another in the region of each container corner 2.

10

The corner guard 1 comprises a caplike corner-protecting element 8 to be fitted externally over the respective container corner 2 and also, according to the invention, an elastic intermediate corner element 15 10 for impact-absorbing arrangement between the corner-protecting element 8 and the container corner 2.

According to figs 3 and 4, the corner-protecting element 8 and also the intermediate corner element 10 20 comprise three respective wall sections 12 and 14 which are each arranged at right angles to one another and are each to be arranged parallel to one of the three container walls 6 adjoining in the region of the container corner 2, and when in the fitted state on the 25 container corner 2 as shown in figs 1 and 2, the wall sections 14 of the intermediate corner element 10 lie flat between the container walls 6 and the wall sections 12 of the corner-protecting element 8.

30 In the preferred embodiment represented, the corner-protecting element 8 is connected releaseably to the intermediate corner element 10, in particular in a nonpositive and/or positive manner by means of a plug-type connection. Furthermore, the corner-protecting 35 element 8, together with the intermediate corner element 10, can also be fastened releaseably in the region of the container corner 2.

Alternatively, however, provision may also be made for

the corner-protecting element 8 to be connected nonreleaseably to the intermediate corner element 10 to form a unit. Furthermore, the corner-protecting element 8, together with the intermediate corner element 10, 5 may also be fastened nonreleaseably on the container corner 2, for example by adhesive bonding.

In the preferred embodiment, the connection of the components requires making provision for the corner- 10 protecting element 8 to be provided in an internal corner 16, which is enclosed by the wall sections 12, with a retaining peg 18 extending at a diagonal angle of approximately 45° to all the wall sections 12 (see fig. 4), onto which peg the intermediate corner element 15 10 can be mounted by way of a corresponding retaining aperture 20. A frictional positive locking engagement is preferably provided here. In addition, the intermediate corner element 10 preferably comprises a sleeve attachment 22 which comprises the retaining 20 aperture 20 and virtually completely encloses the retaining peg 18 of the corner-protecting element 8, with the result that an elastic disconnection of the corner-protecting element 8 from the container 4 is ensured in this region too. Provision is preferably 25 also made here for the corner-protecting element 8, together with the intermediate corner element 10, when in the mounted state on the container corner 2, to be retained by retaining means from the inside of the container in the region of a container corner opening 30 24 (see figs 3 and 4). For this purpose, the retaining peg 18 of the corner-protecting element 8, together with the sleeve attachment 22 of the intermediate corner element 10, protrudes through the container corner opening 24, a retaining screw 26 being screwed 35 to the retaining peg 18 in the inside of the container. This is carried out particularly advantageously by means of an inner elastic pressing element 28 in such a way that the corner-protecting element 8 is disconnected from the container 4 in terms of elastic

impact absorption by way of the intermediate corner element 10 and the pressing element 28, which entails the container walls 6 being contacted exclusively between the elastic components 10 and 28. As is indicated in fig. 4, the elastic pressing element 28 here is in butting connection with the intermediate corner element 10 through the container corner opening 24, preferably via corresponding contoured and negatively contoured surfaces having a positive engagement. The container corner opening 24 here is formed by rectangular or rounded cutouts in each container wall 6, with the result that the actual corner of the container 4 is cut away.

15 In the embodiment represented, the corner-protecting element 8 has externally a partially spherical surface 30 with three flat areas 32 which are each at right angles to one another. Reference should be made particularly to fig. 1 in this regard. This embodiment 20 may thus also be referred to as a spherical corner guard.

The corner-protecting element 8 advantageously consists of a relatively dimensionally stable or hard elastic, 25 preferably fiber-reinforced, plastic. A polyurethane elastomer, as can be obtained for example under the registered trade mark Desmopan, or a polyamide (PA), for example PA6 GF30, is particularly suitable. By contrast, the intermediate corner element 10 may 30 consist of a soft elastic plastic having a Shore A hardness approximately in the range from 50 to 60, preferably approximately 55. A polyurethane (PU) is particularly suitable here. The hardness here may also be selected to be harder or softer to suit the size and 35 the weight of the respective container 4 and the damping properties desired therefor. To ensure good impact absorption here, the effective material thickness of the intermediate corner element 10 should be at least 4 to 5 mm in every region between the

5 container 4 and the corner-protecting element 8. This consequently also applies to the wall sections 14 which should consequently have a thickness of at least approximately 5 mm. The thickness may also be tailored to the size and the weight of the container 4 in order to achieve optimum damping properties.

10 The inner pressing element 28 advantageously consists of a material which is identical to that of the intermediate corner element 10.

15 The invention also relates to the overall container 4, the eight corners 2 of which container are equipped with up to eight associated corner guards 1 according to the invention.

20 The invention is not restricted to the exemplary embodiment which has been represented and described but also comprises all embodiments of equivalent effect within the meaning of the invention. Moreover, the invention is also not restricted to the combination of features defined in claim 1 but may also be defined by any desired other combination of particular features of all the set of individual features disclosed. This 25 means that, in principle, virtually any individual feature of claim 1 can be omitted or replaced by at least one individual feature disclosed elsewhere in the application. In this respect, claim 1 is to be understood merely as a first attempt at formulating an 30 invention.
